Faraday's Day Now Believed to be a Result of Mercury Vapor Poisoning

Even Small Amounts of Vapor Can Cause Severe Mental Problems

It is now believed that mercury vapor poisoning was the cause of Faraday's death, which is mentioned in the text. Faraday had suffered from the disease during the latter part of his life, and it is believed that it contributed to his death in 1867. At that time this poisoning was unknown to modern medicine.

The presence of small amounts of mercury vapor in the air can cause severe poisoning of the body and weaken the immune system, according to Professor L. S. Bellin, director of the Institute of Chemistry at Cornell University, in a statement published in the New York Times.

Even at the present time there are people who suffer from this disease, and the symptoms of mercury poisoning can be recognized by the way it is treated. It is especially harmful to the eyes and hands, which are exposed to it. It is best to have the poison removed by an expert, and to avoid any source of mercury.

Although the cause of the disease was not discovered until two years after its discovery, it was found that the poison, which is present in many substances, can cause serious illness.

The symptoms of mercury poisoning can be recognized by the way it affects the body, and the illness is treated by removing the poison from the body and administering medicine.
