More Than One Hundred Thousand Feet Of Pile Set For New Buildings

Both Concrete and Wooden Piles for New Laboratories

For Laboratories

If all the piles being placed to the southeast of the new Laboratories laboratory were placed end to end, the resulting concrete piling would extend for almost 66,000 feet. This may not be too interesting in itself, but is an item of interest when one considers that the piles are driven in a depth of forty feet. The great length of piles is due to the nature of the ground on the selected site. The great depth of the pile driving was necessary under the existing condition of the soil, and it is one of the advantages of the piles that they are almost a half mile long from one end to the other of the construction.

Two Types of Piles Used

Twelve types of piles were being driven—wood and concrete. About 2800 wood piles, varying in size from 8 by 8 inches to 18 by 18 inches, almost 100,000 feet to be placed, and the concrete piles, with a total length of 18,000 feet, are now driving.

The lumber piles are all of shortleaf pine, ranging in length from the short length to the long length. The short pile was necessary to carry the weight of the building. The long pile is to be driven into a layer of hard sand. The concrete piles are being made with a bed of sand that furnishes a firm bed for the driving of the concrete pile, one and a half feet long, to be placed under the building.
